INTRODUCTION

The decameter-wave radiation from Jupiter has been studied at the Florida State University since 1961. In 1963 the program of study was extended to include spaced-site observations by stations in England and in South Africa. Other stations were established in 1964 in Nigeria, Spain, and Norway. The locations of these stations are shown in Table 1.

All of the observations have been made with the aural monitoring technique with the exception of some made at Grahamstown, South Africa. In every other case an observer was present during the entire period of observation. Jupiter noise was identified according to the following criteria, which have been discussed in more detail elsewhere.¹

1. Jupiter must be in the reception pattern of the antenna.

2. Displacement on recorders must show an obvious increase above the galactic noise level.²

3. The noise must have the characteristic sound.

4. The noise must not tune out over a bandwidth of about 0.5 Mc/s.

5. The noise must not be identifiable as a terrestrial effect, e. g., car ignition, static, power-line interference.

Each event was assigned a subjective identification number 1, 2, or 3, according as the identification was uncertain, probable, or certain in the judgement of the observer on duty at the time. Observing conditions and intensity usually influenced the choice of this number. Some observations at Grahamstown were monitored but identification was also based on a comparison of records taken at two local South African sites separated by about 100 miles.

The usefulness of published data by Warwick and Kreiss,³ and by Douglas and Smith⁴ and the encouragement of a recent NASA contract⁵ to microfilm the Florida State University records for the Goddard Space Science Data Center have stimulated the production of this catalog.

STATION NAME	LOCAL SUPERVISOR	LATITUDE	LONGITUDE
Tallahassee	Mr. C. H. Barrow Department of Physics Florida State University Tallahassee, Florida U. S. A.	30°27'N	84°18'W
Trondheim	Dr. Halvard Torgerson Fysisk Institutt Norges Tekniske Høgskole Trondheim, Norway	63°25'N	10°23'E
St. Osyth	Mr. F. W. Hyde 27 Carlton Road Clacton-on-Sea Essex, England	51°47'N	1°02'E
Valencia	Sr. Don Luis Celda Martinez Centro Meteorologico de Levante Botanico Cavanilles s/n. Valencia 10, Spain	39°30'N	0°21'W
Ibadan	Professor A. J. Lyon Department of Physics University of Ibadan Ibadan, Nigeria	7°40'N	3°50'E
Grahamstown	Mr. G. M. Gruber Department of Physics Rhodes University Grahamstown, South Africa	33°19'S	26°26'E

EQUIPMENT AND REMARKS

Jupiter was observed at Tallahassee during the 1961 apparition using two crossed arrays of eight dipoles at 18.3 and 24.0 Mc/s, a square corner reflector containing a single folded dipole at 18.7 Mc/s, and an east-west-aligned array of four whole-wave center-fed dipoles at 19.5 Mc/s.

Hallicrafters SX-62A receivers were used; the rectified audio outputs from these were fed to Elliott pen-recorders moving at 24 inches per hour during a noise storm at 18.3 and 24.0 Mc/s and at six inches per hour otherwise. The recorder time constant was 0.25 seconds and the receiver bandwidth was 5 kc/s. Jupiter was observed daily for about four hours around transit from April 6 to August 12, 1961 at 18.3, 18.7, and 19.5 Mc/s and from May 5 to August 12 at 24.0 Mc/s.

For observations of Jupiter during 1962 at Tallahassee the antennas were crossed five-element Yagis operating at 16, 18, 22, and 26 Mc/s, an 18 Mc/s square corner reflector and a 38 Mc/s phase-switched interferometer consisting of two square corner reflectors six wavelengths apart.

The output from the Hallicrafters SX-62A receivers was recorded with Elliott recorders moving at six inches per hour. During a noise storm an eight-channel Brush recorder was run at two millimeters per second for the observation of left- and right-hand components of polarization at the four lower frequencies. The Brush recorder time constant was 0.1 seconds.

Observations were made daily for about five hours around transit from April 25 to August 27, 1962.

In 1963 two additional stations were incorporated in the observational program at St. Osyth, England, and Grahamstown, South Africa. The combined observations from these stations, together with those at Tallahassee, allowed monitoring of Jupiter for 16 hours daily from July 17 to November 25, 1963.. Observations at Tallahassee began July 13.

Antenna-receiver-recorder systems used at Tallahassee remained the same as in 1962 with the exception of the 38 Mc/s interferometer which was not used. At St. Osyth a square corner reflector operating at 18 Mc/s fed a Hallicrafters SX-62A receiver. The output was recorded with an Elliott recorder moving at six inches per hour. The recorder constant was 0.25 seconds and the receiver bandwidth about 5 kc/s.

At Grahamstown an eight-dipole broadside array in conjunction with a folded dipole about 100 miles away provided comparison records for identification when no observer was present. The receiver bandwidth was about 8 kc/s and the recorder constant was 0.8 seconds.

In 1964 the spaced-site observations were extended to include stations in Nigeria, Spain, and Norway along a rough north-south line through St. Osyth. Observations were continued at Tallahassee, St. Osyth and Grahamstown.

The antenna-receiver-recorder systems remained unchanged

from 1963 operation at Tallahassee and Grahamstown. At Trondheim, Norway, St. Osyth, England, Valencia, Spain and Ibadan, Nigeria, the antenna-receiver-recorder systems were standardized. An 18 Mc/s four-element Yagi fed a Hallicrafters S-108 receiver. The receiver output was recorded by an Elliott recorder operating at 24 inches per hour during a noise storm but at six inches per hour at other times in the absence of high speed recorders which were not available at that time. The recorder constant was 0.25 seconds and the receiver bandwidth was 6 kc/s.

Observations were made from August 1 to December 15, 1964, at all outstations. At Tallahassee the observing season was from July 27, 1964, to January 14, 1965, except at 18 Mc/s which was inoperative after December 31, 1964.

REMARKS ON TABULATION OF THE DATA

14636

During the observing season daily log sheets are kept in which are noted the date the watch ends, the beginning and ending times in Universal Time of observation and any activity, the identification number, the System II Central Meridian Longitude, the Julian date, the average of the three largest Jupiter noise deflections, and the average galactic background level. Later this information is transferred directly to IBM punch cards.

For this catalog a program was devised which prints out the year, frequency, and station at which the observations were made. Beneath are the month, day, begin and end time in Universal Time of observation and activity, the identification number, and the beginning and ending time of activity in System III (1957) Central Meridian Longitude.

A complete list of 18 Mc/s observations at Tallahassee is provided for each year. In addition there is a combined list of outstation observations during 1964 in which is included only activity reported simultaneously or nearly simultaneously at two or more stations. This restriction is imposed as an additional identification criterion. *Author*

For other frequencies used at Tallahassee and for individual outstations a list containing reported activity only is included with a notation of days on which there was no

observation at a particular frequency or outstation. More specific information regarding inactive periods at these frequencies and stations may be obtained upon request from the Florida State University Radio Observatory. A smoothed probability histogram of each year's 18 Mc/s observations is included. The 1964 histogram is a composite of the Tallahassee and the combined outstation observations.

1. Barrow, C. H. (1964) Polarization Observations of Jupiter at Decameter Wavelengths, *Icarus*, 3, 66
2. At a recent conference of Jupiter observers at the NASA Goddard Space Flight Data Center, Greenbelt, Maryland, April, 1965, the following suggestions were made regarding the definitions of an event and of a burst. An event is a signal of Jovian origin whose intensity is equal to or greater than three times the rms system noise in any given five-minute interval measured from Oh U.T. A burst is a signal of Jovian origin whose intensity is equal to or greater than three times the rms system noise on a time scale of one second or longer. These approximate to the considerations implied by criterion 2.
